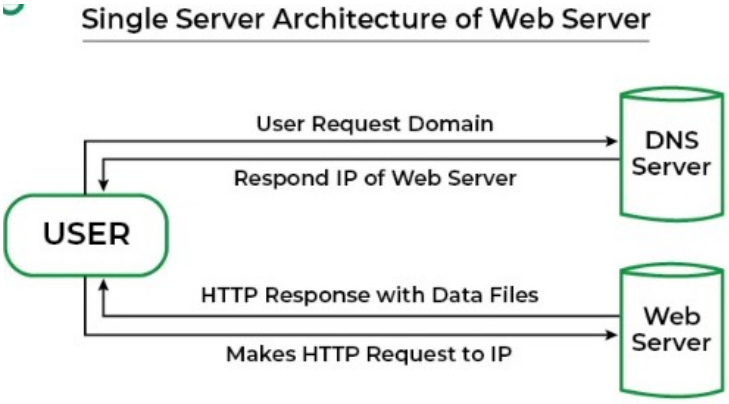
**Role of Web Server Software**: Web server software delivers web content, such as HTML pages, images, and dynamic data, to clients over HTTP or HTTPS by processing requests and managing connections efficiently. It handles tasks like serving static files, executing dynamic scripts, load balancing, and securing traffic via SSL/TLS. Common examples include Apache2, IIS, and NGINX, each optimized for different workloads

A web server is a software or hardware system that stores, processes, and delivers web content to users over the internet. It is a core component of the client–server model, handling requests from browsers and returning the required resources.

- Web servers use the HTTP protocol to manage communication on the web.
- A browser sends an HTTP request to the server when you enter a website's URL.
- The server responds by delivering the requested web page for the browser to display.

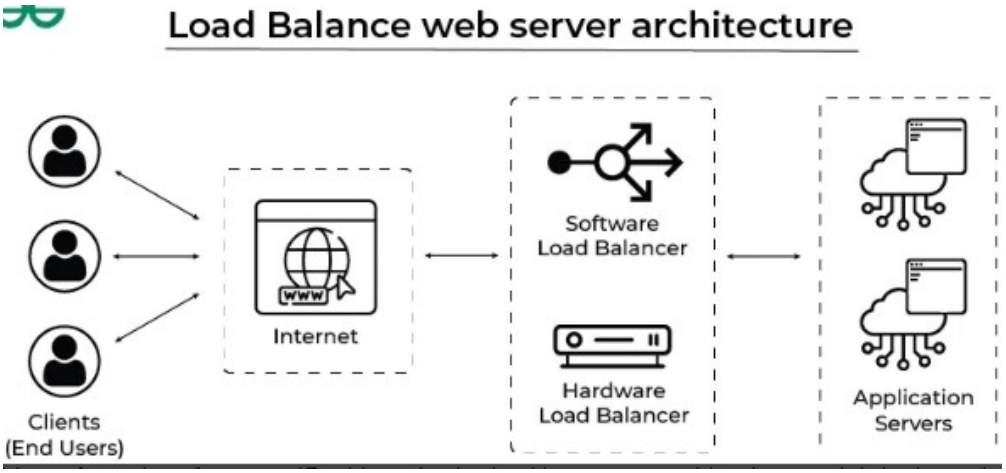
Web server architecture refers to the structure and design of web servers, outlining how they handle incoming requests and deliver web content. There are two main approaches to web server architecture:

**1. Single-Tier (Single Server) Architecture:** In a single-tier architecture, a single server is responsible for both processing requests and serving web content. This is suitable for small websites or applications with low traffic. However, it has limitations in terms of scalability and fault tolerance. If the server goes down, the entire service becomes unavailable.



single-server-arch-web-server

**2. Multi-Tier (Load-Balanced) Architecture:** In a multi-tier architecture, multiple servers are used to distribute the workload and ensure high availability. This approach often involves load balancers that evenly distribute incoming requests across a cluster of web servers. Each server can serve web content independently, and if one server fails, the load balancer redirects traffic to healthy servers, ensuring uninterrupted service.



load-balancer-ser

**Working of Web Servers:** There are several types of web servers, each designed for specific purposes

Apache HTTP Server: Apache is one of the most popular open-source web servers globally, known for its flexibility and robustness. It's highly customizable and supports a wide range of modules and extensions.

Nginx: Nginx is another widely used web server known for its speed and efficiency in handling concurrent connections.

Microsoft Internet Information Services (IIS): IIS is a web server developed by Microsoft for Windows servers. It's commonly used for hosting websites and web applications built on Microsoft technologies like ASP.NET.

LiteSpeed: LiteSpeed is a commercial web server known for its high performance and security features. It's often used in hosting environments where speed and security are paramount.

Built-In Web Server Capabilities

Web servers offer a range of features, including:

**Content Hosting:** They store and serve web content, including HTML pages, images, videos, and other multimedia files.

**Security:** Web servers implement various security mechanisms to protect against unauthorized access and cyberattacks.

**Load Balancing:** Some web servers can distribute incoming traffic across multiple server instances to ensure optimal performance and availability.

**Logging and Monitoring:** They provide tools to track and analyze server performance, user access, and error logs.

**Caching:** Web servers can cache frequently accessed content to reduce server load and improve response times.

Benefits of Web Servers

**1. Scalability:** Web servers can handle a large number of simultaneous connections, making them suitable for high-traffic websites.

**2. Reliability:** They are designed for continuous operation and can recover from failures gracefully.

**3. Security:** Web servers include security features to protect against common web threats like DDoS attacks and SQL injection.

**4. Customization:** Web server configurations can be tailored to specific application requirements.

**Steps to Use Web Server**

Step 1: Choose a Web Server Software

Select web server software that suits your needs. Apache, Nginx, IIS, httpd, and LiteSpeed are popular choices, depending on your requirements.

Step 2: Install and Configure

Install the chosen web server software on your server or hosting environment. Configure it by specifying settings such as document root, security rules, and virtual hosts.

Step 3: Upload Your Website

Upload your website files to the server. These typically include HTML, CSS, JavaScript, and any other assets like images or videos.

Step 4: Test Your Website

Test your website by accessing it through a web browser. Ensure that it loads correctly and all functionalities work as expected.

Step 5: Monitor and Maintain

Regularly monitor your web server for performance, security, and updates. Implement security measures to protect against threats.

# Key Comparison

| Feature | Apache2 | IIS | NGINX |
|---|---|---|---|
| Architecture | Process/thread-based (MPM) | Integrated Windows processes | Event-driven, asynchronous |
| Performance (Static) | Good, higher resource use | Solid in Windows ecosystem | Excellent, low memory |
| Performance (Dynamic) | Native module support | Strong with ASP.NET | Needs external like PHP-FPM |
| Flexibility | High via .htaccess/modules | GUI ease, Microsoft integration | Centralized config |
| Scalability | Horizontal via load balancers | Good in Windows | High concurrency |
| Platform | Cross-platform (Linux preferred) | Windows-only | Cross-platform |

**Server Side Scripting Languages:** Web server-side scripting languages generate dynamic content on the server before sending it to the client, handling tasks like database interactions, user authentication, and logic processing. Popular options include PHP, Python, Node.js (JavaScript runtime), Java, Ruby, and C#. These enable interactive web applications beyond static HTML.

| Language | Performance | Ease of Learning | Scalability & Use Cases | Frameworks & Ecosystem |
|---|---|---|---|---|
| PHP | Good with optimization | Beginner-friendly | High for dynamic sites, broad server support | Laravel, Symfony |
| Python | Solid for most apps | Very easy, readable syntax | Versatile: web, data, AI; scalable | Django, Flask |
| Node.js | Excellent for I/O-heavy | Moderate if knowing JS | Real-time apps, high concurrency | Express |
| Java | High, enterprise-grade | Steeper curve | Large-scale, secure apps | Spring |
| Ruby | Good for rapid dev | Simple syntax | Prototyping, web services | Rails, Sinatra |
| C# | Optimized, fast | Easy for C++ users | Microsoft-integrated web logic | ASP.NET |

**Intro of PHP:** Introduction Back in 1994, Rasmus Lerdorf unleashed the very first version of PHP. However, now the reference implementation is now produced by The PHP Group. The term PHP originally stood for Personal Home Page but now it stands for the recursive acronym: Hypertext Preprocessor. PHP 4 and PHP 5 are distributed under the PHP Licence v3.01, which is an Open Source licence certified by the Open Source Initiative. PHP started out as a small open source project that evolved as more and more people found out how useful it was. Rasmus Lerdorf unleashed the first version of PHP way back in 1994. PHP is a recursive acronym for "PHP: Hypertext Preprocessor". PHP is a server side scripting language that is embedded in HTML. It is used to manage dynamic content, databases, session tracking, even build entire e-commerce sites. It is integrated with a number of popular databases, including MySQL, PostgreSQL, Oracle, Sybase, Informix, and Microsoft SQL Server.

PHP is pleasingly zippy in its execution, especially when compiled as an Apache module on the Unix side. The MySQL server, once started, executes even very complex queries with huge result sets in record-setting time. PHP supports a large number of major protocols such as POP3, IMAP, and LDAP. PHP4 added support for Java and distributed object architectures (COM and CORBA), making n-tier development a possibility for the first time. PHP is forgiving: PHP language tries to be as forgiving as possible.

PHP Syntax is C-Like. Common Uses of PHP PHP performs system functions, i.e. from files on a system it can create, open, read, write, and close them. The other uses of PHP are: PHP can handle forms, i.e. gather data from files, save data to a file, thru email you can send data, return data to the user. You add, delete, modify elements within your database thru PHP. Access cookies variables and set cookies. Using PHP, you can restrict users to access some pages of your website. It can encrypt data.

**Why PHP?**

**Compatible with almost all servers used nowadays:** A web server is an information technology that processes requests via HTTP, the basic network protocol used to distribute information on the World Wide Web. There exist many types of web servers that servers use. Some of the most important and well-known are: Apache HTTP Server, IIS (Internet Information Services), lighttpd, Sun Java System Web Server etc. PHP is compatible with all these web servers and many more. PHP will run on most platforms Unlike some technologies that require a specific operating system or are built specifically for that, PHP is engineered to run on various platforms like Windows, Mac OSX, Linux, Unix etc)

**PHP supports such a wide range of databases** An important reason why PHP is so used today is also related to the various databases it supports (is compatible with). Some of these databases are: DB++, dBase, Ingres, Mongo, MaxDB, MongoDB, mSQL, Mssql, MySQL, OCI8, PostgreSQL, SQLite, SQLite3 and so on.

**PHP is free to download and open source** Anyone can start using PHP right now by downloading it from php.net. Millions of people are using PHP to create dynamic content and database-related applications that make for outstanding web systems. PHP is also open source, which means the original source code is made freely available and may be redistributed and modified.

**Easy to learn & large community** PHP is a simple language to learn step by step. This makes it easier for people to get engaged in exploring it. It also has such a huge community online that is constantly willing to help you whenever you’re stuck (which actually happens quite a lot).

## PHP Magic constants

PHP provides a large number of predefined constants to any script which it runs.

There are five magical constants that change depending on where they are used. For example, the value of __LINE__ depends on the line that it's used on in your script. These special constants are case-insensitive and are as follows:

The following table lists a few "magical" PHP constants along with their description:

| Name | Description |
|---|---|
| __LINE__ | The current line number of the file. |
| __FILE__ | The full path and filename of the file. If used inside an include, the name of the included file is returned. Since PHP 4.0.2, __FILE__ always contains an absolute path whereas in older versions it contained relative path under some circumstances. |
| __FUNCTION__ | The function name. (Added in PHP 4.3.0) As of PHP 5 this constant returns the function name as it was declared (case-sensitive). In PHP 4 its value is always lowercased. |
| __CLASS__ | The class name. (Added in PHP 4.3.0) As of PHP 5 this constant returns the class name as it was declared (case-sensitive). In PHP 4 its value is always lowercased. |
| __METHOD__ | The class method name. (Added in PHP 5.0.0) The method name is returned as it was declared (case-sensitive). |
